

Some major implications of climatic fluctuations on water management

Mahmoud A. Abu-Zeid and Asit K. Biswas

Climatic fluctuations affect water management in a variety of ways. Much emphasis has been placed in recent years on climatic changes that may occur in the future due to global warming resulting from increases in greenhouse gases. If and when global warming takes place, water availability and use patterns will most certainly change. At our present state of knowledge it is not possible to predict the onset of climatic changes, including their magnitude and spatial distribution, with any degree of confidence so that they can be explicitly incorporated into water management in a cost-effective manner. The problem of climatic fluctuations appears to be more complex than the water resources profession has so far realized. Development of new methodologies to deal efficiently with climatic fluctuations is urgently needed.

The issue of climatic change and its possible impacts on mankind has become a major topic for discussion in recent months. The possibility of global warming due to the greenhouse effect is now firmly on the world's scientific and political agenda. Numerous meetings on climatic change are now being held all over the world, which are scientific, political or even pseudo-scientific in nature. Unquestionably ozone depletion and global warming have primarily been responsible for rekindling the interest of the general public in various environmental issues, to a level that has not been witnessed since the early 1970s.

Much has been said and written in recent months about the impacts of potential climatic changes on global food production, primarily through the modification of prevailing water regimes caused by climatic changes. Many predictions have been made, mostly catastrophic, on how global food production is

going to suffer due to changing patterns of rainfall and temperature, and on the attendant problems facing water control and management. There is no question that if existing rainfall and temperature patterns change during forthcoming decades, there could be important implications for agricultural production and water management, at global as well as regional and national levels, depending on the rate, magnitude and spatial distribution of such changes.

Climatic fluctuations and water management

While climatic fluctuations affect water management in a variety of ways, it should be clearly noted at the outset that climate is one of the many factors, albeit an important one, that have major impacts on the availability and use of water resources. Among other important factors that affect water management are population levels and densities; extent and level of economic activities, especially in terms of agricultural and industrial development; standard of living and efficiency of water use. These issues are generally closely interrelated.
