

Clinical Applications of Hypnosis to Three Psychosomatic Disorders

Frank A. De Piano and Herman C. Salzberg
University of South Carolina

Studies of hypnosis in the treatment of skin disorders, headaches, and asthma were reviewed in terms of outcomes and methodological soundness. Some studies focused on changing physiological functions, others on increasing insight in their patients, and still others on altering patients' perceptions of their symptoms. Methodological weaknesses included lack of control groups, nonrandom assignment of patients to treatment conditions, and confounding of treatment effects or lack of control for placebo effects. Additional weaknesses centered around the use of single outcome measures and the failure to assess the specific roles of mediating variables. Most of the studies reviewed showed positive treatment effects. However, there is equivocal evidence that hypnosis can directly influence autonomic functioning. Hypnosis may be valuable in facilitating one's capacity to gain insight into how one's symptoms developed and are maintained. In addition, hypnotic procedures have resulted in some success when used to indirectly alleviate symptoms by altering how individuals perceive their disorders and how these disorders affect their lives.

Hypnosis has become an accepted mode of treatment in both medicine and clinical psychology. Its judicious use was endorsed by the American Medical Association in 1958 and by the British Medical Association in 1955. In 1960, the American Psychological Association sanctioned its use in clinical practice (Hilgard, 1968). Several societies are devoted to the professional study of hypnosis, and both psychology and medical training programs offer courses in it.

This article reviews the published reports of the clinical application of hypnosis to skin disorders, headaches, and asthma. The review covers the period from 1967 to 1977 comprehensively, as well as reports prior to 1967 that had a substantial impact on the field.

Hypnosis is most frequently associated with suggestibility. Barber (1974) and his collaborators have, in essence, equated the two by arguing that subjects, when given direct suggestions without a hypnotic induc-

tion, displayed behavior similar to that of subjects given a formal induction. Other investigators have adhered to the conceptualization of hypnosis as an altered state of consciousness (Fromm, 1977; Hilgard, 1968). In either case, its investigation as a treatment adjunct for psychosomatic disorders would be justifiable. However, expectations for success might vary with the definition that the investigator accepts.

Although there is disagreement about which specific ailments are psychosomatic and which are primarily organic, it is widely accepted that psychosomatic disorders are etiologically related to or are exacerbated by psychological factors, even though physical symptoms are present and medical intervention is often necessary. Some practitioners argue that illness is always a psychosomatic event. Others merely label a disorder psychosomatic when physical causes are not readily identifiable. Obviously, an investigator's view of a disorder as psychosomatic would influence the decision to use hypnosis in a particular case, which might, in turn, affect the outcome of treatment.
