

Acquired Aphasia in Children

Isabelle Rapin, MD

There are few disorders in child neurology, even in medicine, about which thinking has changed more drastically over the last quarter century than acquired aphasia in children. The thinking at the time is exemplified by Lenneberg's 1967 seminal book *Biological Foundations of Language*,¹ which contrasts childhood acquired aphasia with aphasia in adults. Lenneberg summarized the literature and, based on his review of 17 adequate reports from the literature and eight personal cases, divided children into four groups. He stated that when a focal brain lesion is sustained between ages 20 and 36 months, children recapitulate all the stages of language learning, from vocalization and babbling to single words, primitive two word phrases, etc until perfect speech is achieved, and he concluded that recovery is due to reacquisition rather than symptom reduction. He reported that between ages 3 and 4 years, aphasic symptoms last no more than a few weeks and that aphasia is invariably expressive. He stated that between 4 and 10 years of age, children evince the classic aphasic syndromes of adults, except that fluent "logorrheic" receptive aphasia does not occur; complete recovery is universal, although recovery may extend over several years, in contrast to adults, in whom recovery is minimal after 5 months. After puberty, residual symptoms, including word finding difficulty and verbal and phonemic paraphasic errors may persist, and after the midteens, all the characteristics of adult aphasia prevail.

The advent of modern neuroimaging and more rigorous neuropsychologic and psycholinguistic study of childhood acquired aphasia, together with the publication of a number of individual cases, several case series, and two books^{2,3} have changed our views substantially since Lenneberg's book. I will focus here on the following issues: (1) cerebral maturation and lateralization; (2) site of lesion and age of the child; (3) cerebral plasticity and recovery from aphasia; (4) subtypes of aphasia; and (5) acquired epileptic aphasia.

CEREBRAL MATURATION AND LATERALIZATION

The question of whether cerebral dominance for language develops progressively or is innate was a burning issue in Lenneberg's time. The then-prevalent view was that the two hemispheres are equipotential at birth and that hemispheric lateralization for language develops progressively during childhood. Two arguments in support of the hypothesis were, first, that virtually all children with a congenital or infantile hemiplegia are verbal and, it was said, acquire language at the expected age regardless of the side of the lesion, and second, that hemispherectomy, whether performed on the right or the left, does not result in aphasia, provided the original lesion was sustained in infancy.⁴

The idea of progressive maturation of cerebral dominance for language has become largely discredited on anatomic, physiologic, and behavioral evidence that was unavailable to Lenneberg. Witelson and Pallie⁵ found that the asymmetry in the planum temporale described by Geschwind and Levitsky⁶ in the majority of adult brains is already discernible in the neonate and, according to Wada et al,⁷ in the fetus at 20 weeks of gestation. There are already demonstrable interhemispheric differences in the amplitude of auditory event-related potentials in neonates, with speech eliciting larger-amplitude responses on the left, and music doing so on the right.⁸ Bertoncini et al⁹ were able to show in neonates a right ear (left hemisphere) advantage for dichotically presented speech sounds and a left ear (right hemisphere) advantage for music.

SITE OF LESION AND AGE OF THE CHILD

It was also believed at the time that aphasia after right-sided lesions was much more common in children than in adults: Basser⁴ reported that 47% of right hemispheric lesions sustained after age 2 years resulted in aphasia—certainly less than the 85% he reported after left-sided lesions but many more than would be the case in adults, virtually all of whom are now known to be left-brained for language if right-handed, and at least two thirds of whom are substantially left-brained for language even if left-handed. Woods and Teuber,¹⁰ who studied 65 children aged 2 to 14 years with strictly documented nonprogressive unilateral brain lesions, noted that 25 (74%) of the 34 with left-sided lesions were aphasic, compared to four (13%) of the 31, two of them left-handed, with right-sided lesions. They attributed the earlier reports of a

Acquired Aphasia In Children:

Acquired Aphasia in Children Isabel Pavão Martins, A. Castro-Caldas, Hugo R. van Dongen, Anne van Hout, 2012-12-06 One of the most fascinating problems in Behavioural Neurology is the question of the cerebral organization for language during childhood. Acquired aphasia in children, albeit rare, is a unique circumstance in which to study the relations between language and the brain during cerebral maturation. Its study further contributes to our understanding of the recovery processes and brain plasticity during childhood. But while there is a great amount of information and experimental work on brain-behaviour relationships in adult subjects, the literature about the effects of focal brain lesions in children is both exiguous and scattered throughout scientific journals and books. We felt it was time to organize a meeting where scientists in this field could compare their experiences and discuss ideas coming from different areas of research. A workshop on Acquired Aphasia in Children was held in Sintra, Portugal, on September 13-15, 1990, and attended by 44 participants from 13 different countries. The atmosphere was relaxed and informal, and the group was kept small to achieve this effect. It was a very lively and pleasant meeting. Some consensus was indeed arrived at concerning methodological problems, definition of terms, and guidelines for future research. The main contributions are collected in this book, which we hope will serve the scientific community as a reference work on Childhood Aphasia. I. P. M. A. C. C. *Children with Acquired Aphasias* Janet Lees, 2005. A total of 25 cases of children with these disorders is described, and their management explained in detail, most from onset and including long-term outcomes. *Patient-based Approaches to Cognitive Neuroscience* Todd E. Feinberg, Martha J. Farah, 2000. Part I covers the history, principles, and methods of patient-based neuroscience: lesion method, imaging, computational modeling, and anatomy. Part II covers perception and vision: sensory agnosias, disorders of body perception, attention, and neglect; disorders of perception and awareness; and misidentification syndromes. Part III covers language: aphasia, language disorders in children, specific language impairments, developmental dyslexia, acquired reading disorders, and agraphia. Part IV covers memory: amnesia and semantic memory impairments. Part V covers higher cognitive functions: frontal lobes, callosal disconnection, split-brain, skilled movement disorders, acalculia, dementia, delirium, and degenerative conditions including Alzheimer's disease, Parkinson's disease, and Huntington's disease. *Acquired Childhood Aphasia with Focus on Landau-Kleffner Syndrome* Stefanie Jansing, 2009-07. Seminar paper from the year 2007 in the subject English Pedagogy/Didactics/Literature Studies, grade 1-3, University of Münster. English Seminar course: Cognitive Linguistics. Language: English. Abstract: Aphasia is the neurological term for any language disorder that results from brain damage caused by disease or trauma. 1. The disorder is not exclusively found in adults but may also occur in children. To lose the ability to understand and produce language may be a major catastrophe for children and has enormous consequences for their whole life, even if speech is regained after some time. 2. Therefore, it is astonishing how little is known about the subject and how controversially it is discussed in literature. This paper introduces into acquired childhood aphasia with focus on a syndrome.
