

An **anti-lock braking system (ABS)** is a safety anti-skid braking system used on aircraft and on land vehicles, such as cars, motorcycles, trucks and buses ABS operates by preventing the wheels from locking up during braking.

ABS is an automated system that uses the principles of [threshold braking](#) and [cadence braking](#), techniques which were once practised by skilful drivers before ABS braking systems were widespread. ABS operates at a much faster rate and more effectively than most drivers could manage. Although ABS generally offers improved vehicle control and decreases stopping distances on dry and some slippery surfaces.

❖ OPERATION:-

- The anti-lock brake controller is also known as the CAB (Controller Anti-lock Brake).
- Typically ABS includes a central [electronic control unit](#) (ECU), four [wheel speed sensors](#), and at least two hydraulic valves within the brake [hydraulics](#). The ECU constantly monitors the [rotational speed](#) of each wheel; if it detects the wheel rotating significantly slower than the speed of the vehicle, a condition indicative of impending wheel lock, it actuates the valves to reduce hydraulic pressure to the brake at the affected wheel, thus reducing the braking force on that wheel; the wheel then turns faster.
- ABS equipment may also be used to implement a [traction control system](#) (TCS) on acceleration of the vehicle. If, when accelerating, the tire loses traction, the ABS controller can detect the situation and take suitable action so that traction is regained. More sophisticated versions of this can also control throttle levels and brakes simultaneously.
- The speed sensors of ABS are sometimes used in indirect [tire pressure monitoring system](#) (TPMS), which can detect under-inflation of tire(s) by difference in rotational speed of wheels.
