**Tandem Queuing Model for Production Line with Downtimes** Ruth Sagron, 2017 Queuing networks are frequently used to predict the performance of complex manufacturing systems Yet existing queuing network approximations cannot properly cope with downtime events e g set up maintenance in manufacturing lines These events involve significant interference among classes and generate non renewable flows with very high variability while causing starvation as well as blocking of bottleneck queues Frequently simulation models are used in such practical situations Yet they are expensive and time consuming to model update and run We consider systems with downtimes as multi class systems in open and tandem queuing networks with class dependent service and routing in which Class 1 represents the class of interest and Class 2 represents the downtime events We focus our analysis on a tandem queue in which the last queue is a bottleneck which may experience starvation thus

blocking is not in our scope. Two-moment decomposition, which is a common method for performance prediction in queueing networks, is the natural choice. Thus, the primary objective of this work is improving existing multiclass decomposition methods with deterministic routing. Decomposition methods decompose the queueing network into a set of separate queues having independent arrival processes. Since in a tandem topology the departure from one queue is the arrival to the next, the focus in this work is turned to departure processes. First, we investigate these processes in a single queue. Then, we analyze and improve the second-moment approximations of the departure processes within the tandem queues. Here, in addition to the Class 1 arrival and service processes, interference created by Class 2 is taken into consideration; therefore, analyzing the departure process for each class is needed. In the first phase of the work, we investigate the inter-departure time distribution in a  $G/G/1$  queue. Initially, we exploit the probabilistic interpretation of the phase-type distributions for deriving an explicit expression of the Laplace-Stieltjes transform (LST) of the inter-departure times in various cases of  $PH/G/1$  queues. Then, we use these results in expressing the LST of the inter-departure times in more general queues. By the specific result of a  $C_m/G/1$  queue, we show that the LST of inter-departure times of any  $K_m/G/1$  queue can be expressed explicitly. In addition, we show that the LST of inter-departure times of any  $G/G/1$  queue with continuous inter-arrival distribution can be approximated appropriately by a  $PH/G/1$  queue. These results play an important role in improving the accuracy of approximations used for studying and predicting the performance of open queueing networks. In our work, these results improve the efficiency of our approximation method, as is detailed in the third phase. In the second phase of the work, we introduce the bottleneck phenomenon caused by interference, e.g., by downtimes within the network, while improving the basic structure of class departure variability. Our analysis illustrates that this variability can be expressed as the sum of two components: the first component reflects the within-class effect (the variability caused by the class own inter-arrival and service time distributions), and the second reflects the between-class effect (the variability caused by interactions with other classes). We integrate the existing decomposition methods with two variability functions, one for each effect. Our analysis shows that the within-class effect can be approximated by the existing variability function proposed by Kim (2005), while the between-class effect requires a new function. In this phase, we propose an initial function for the latter effect, requiring high computation efforts due to many sub-simulations. In the third phase of the work, we introduce an advanced function for the between-class effect: Regression-Based Variability Function. This function depends on downstream waiting time and exploits the analysis of departure from a single queue while employing the developments in the first phase of this work. The Regression-Based Variability Function model significantly reduces computation efforts, except for one sub-simulation for each traffic intensity level. With this model, we also show that predicting the performance of  $n$  tandem queues is possible by reducing the focus to 2-tandem queues for each traffic intensity level. Our proposed method has been examined via simulation for scenarios of  $n$  tandem queues with bottleneck under downtimes with FCFS and priority policies. In such scenarios, the results demonstrate a
