

The Elemental Analysis of Geological Materials

Elegant solutions from SPECTRO Analytical Instruments

Elemental analysis is one of the most important investigative tools in geology, vital in mineral exploration, extraction process control and environmental studies. Energy Dispersive X-Ray Fluorescence (EDXRF) spectrometry provides a convenient, rapid method of analysis for rocks, exploration samples, minerals, ores, concentrates and tailings, usually with far less sample preparation than that required for other techniques. The SPECTRO Analytical Instruments catalogue includes EDXRF instruments with characteristics optimized for this field of work. The SPECTRO XEPOS is the ideal multi-role instrument for routine analysis of all relevant elements from Sodium to Uranium, and the SPECTRO XEPOS HE is optimized for the highest sensitivity when determining minor and trace elements, especially the economically and environmentally important "medium" and "heavy" elements. The handheld and truly portable SPECTRO xSDRT ECM has very short measuring times, making it ideal for field investigations and surveys, where many measurements may need to be taken as quickly and efficiently as possible.

So-called "matrix effects" are common in geological analysis by EDXRF, and if ignored can cause significant quantitative errors. Advanced EDXRF technology and sophisticated calibration techniques are employed in SPECTRO EDXRF instruments to minimize and compensate for matrix effects. This means that systems pre-calibrated at the factory will give accurate results, even on samples with widely differing matrices, making these instruments exceptionally easy to set up and use. This paper illustrates the high quality of results obtainable with these instruments using straightforward and well proven sample preparation techniques.

EDXRF FOR GEOLOGICAL ANALYSIS – GENERAL CONSIDERATIONS

EDXRF analysis has one huge advantage over many other methods for the analysis of geological samples, namely that it can usually be performed directly on the solid or on the powdered material, thereby avoiding the time-consuming, costly and potentially hazardous process of dissolving the sample. It is this, combined with the portability of some modern instrumentation, which makes EDXRF especially suitable for analysis in the field. Dissolving the sample, on the other hand, has the benefit that it effectively removes the analyte elements from the matrix in which they occur. It is well known that the matrix can have a very significant effect on EDXRF results, so the analytical signal from the same concentration of a given element could be different in different matrices – for example in acidic, intermediate or igneous rocks. Geological samples often contain a wide range of elements at vastly differing concentrations, from major components to traces. Various inter-element interferences can therefore also occur and must be considered. The analytical accuracy of an EDXRF system will depend to a significant degree on its ability to deal with these effects. The physical nature of the sample can also affect the quality of results.
