

Laser Diode - Construction & Working

Blue Laserlight Emit Diodes 2

James Pawley

Blue Laserlight Emit Diodes 2:

Blue Laser and Light Emitting Diodes II, 1998 **Tailoring the Emission of Stripe-array Diode Lasers with External Cavities to Enable Nonlinear Frequency Conversion** Andreas Jechow, 2009

A huge number of applications require coherent radiation in the visible spectral range. Since diode lasers are very compact and efficient light sources, there exists a great interest to cover these applications with diode laser emission. Despite modern band gap engineering, not all wavelengths can be accessed with diode laser radiation. Especially in the visible spectral range between 480 nm and 630 nm, no emission from diode lasers is available yet. Nonlinear frequency conversion of near infrared radiation is a common way to generate coherent emission in the visible spectral range. However, radiation with extraordinary spatial, temporal, and spectral quality is required to pump frequency conversion. Broad area (BA) diode lasers are reliable, high power light sources in the near infrared spectral range. They belong to the most efficient coherent light sources with electro-optical efficiencies of more than 70%. Standard BA lasers are not suitable as pump lasers for frequency conversion because of their poor beam quality and spectral properties. For this purpose, tapered lasers and diode lasers with Bragg gratings are utilized. However, these new diode laser structures demand additional manufacturing and assembling steps that make their processing challenging and expensive. An alternative to BA diode lasers is the stripe array architecture. The emitting area of a stripe array diode laser is comparable to a BA device, and the manufacturing of these arrays requires only one additional process step. Such a stripe array consists of several narrow striped emitters realized with close proximity. Due to the overlap of the fields of neighboring emitters or the presence of leaky waves, a strong coupling between the emitters exists. As a consequence, the emission of such an array is characterized by a so-called supermode. However, for the free-running stripe array mode competition between several supermodes occurs because of the lack of wavelength stabilization. This leads to power fluctuations, spectral instabilities, and poor beam quality. Thus, it was necessary to study the emission properties of those stripe arrays to find new concepts to realize an external synchronization of the emitters. The aim was to achieve stable longitudinal and transversal single mode operation with high output powers, giving a brightness sufficient for efficient nonlinear frequency conversion. For this purpose, a comprehensive analysis of the stripe array devices was done here. The physical effects that are the origin of the emission characteristics were investigated theoretically and experimentally. In this context, numerical models could be verified and extended. A good agreement between simulation and experiment was observed. One way to stabilize a specific supermode of an array is to operate it in an external cavity. Based on mathematical simulations and experimental work, it was possible to design novel external cavities to select a specific supermode and stabilize all emitters of the array at the same wavelength. This resulted in stable emission with 1 W output power, a narrow bandwidth in the range of 2 MHz, and a very good beam quality with M² < 1.5.
