Dynamical Systems In Population Biology:

Dynamical Systems in Population Biology Xiao-Qiang Zhao, 2013-06-05 Population dynamics is an important subject in mathematical biology. A central problem is to study the long term behavior of modeling systems. Most of these systems are governed by various evolutionary equations such as difference, ordinary functional and partial differential equations (see e.g. [165, 142, 218, 119, 55]). As we know, interactive populations often live in a fluctuating environment. For example, physical environmental conditions such as temperature and humidity and the availability of food, water and other resources usually vary in time with seasonal or daily variations. Therefore, more realistic models should be nonautonomous systems. In particular, if the data in a model are periodic functions of time with commensurate period, a periodic system arises. If these periodic functions have different minimal periods, we get an almost periodic system. The existing reference books from the dynamical systems point of view mainly focus on autonomous biological systems. The book of Hess [106] is an excellent reference for periodic parabolic boundary value problems with applications to population dynamics. Since the publication of this book, there have been extensive investigations on periodic, asymptotically periodic, almost periodic and even general nonautonomous biological systems, which in turn have motivated further development of the theory of dynamical systems. In order to explain the dynamical systems approach to periodic population problems, let us consider as an illustration two species periodic competitive systems $\frac{dU_i}{dt} = U_i(U_1 + U_2 - 0)$.

Dynamical Systems in Population Biology Xiao-Qiang Zhao, 2017-04-11 This research monograph provides an introduction to the theory of nonautonomous semiflows with applications to population dynamics. It develops dynamical system approaches to various evolutionary equations such as difference, ordinary functional and partial differential equations and pays more attention to periodic and almost periodic phenomena. The presentation includes persistence theory, monotone dynamics, periodic and almost periodic semiflows, basic reproduction ratios, traveling waves and global analysis of prototypical population models in ecology and epidemiology. Research mathematicians working with nonlinear dynamics, particularly those interested in applications to biology, will find this book useful. It may also be used as a textbook or as supplementary reading for a graduate special topics course on the theory and applications of dynamical systems. Dr. Xiao-Qiang Zhao is a University Research Professor at Memorial University of Newfoundland, Canada. His main research interests involve applied dynamical systems, nonlinear differential equations and mathematical biology. He is the author of more than 100 papers and his research has played an important role in the development of the theory and applications of monotone dynamical systems, periodic and almost periodic semiflows, uniform persistence and basic reproduction ratios.

[Dynamical Systems and Population Persistence](#) Hal L. Smith, Horst R. Thieme, 2011 The mathematical theory of persistence answers questions such as which species in a mathematical model of interacting species will survive over the long term. It applies to infinite dimensional as well as to finite dimensional dynamical systems and to discrete time as well as to continuous time semiflows. This monograph provides a self-contained treatment of persistence theory that is

accessible to graduate students The key results for deterministic autonomous systems are proved in full detail such as the acyclicity theorem and the tripartition of a global compact attractor Suitable conditions are given for persistence to imply strong persistence even for nonautonomous semiflows and time heterogeneous persistence results are developed using so called average Lyapunov functions Applications play a large role in the monograph from the beginning These include ODE models such as an SEIRS infectious disease in a meta population and discrete time nonlinear matrix models of demographic dynamics Entire chapters are devoted to infinite dimensional examples including an SI epidemic model with variable infectivity microbial growth in a tubular bioreactor and an age structured model of cells growing in a chemostat Publisher s description
