The electronic circuit is a proud child of twentieth century natural science. In a hundred short years it has developed to the point that it now enhances nearly every aspect of human life. Yet our basic understanding of electronic circuit operation, electronic circuit theory, has not made significant progress during the semiconductor industry's explosive growth from the 1950s to the present. This is because the electronic circuit has never been considered to be a challenging research subject by physicists. Linear passive circuit theory was established by the late 1940s. After the advent of the semiconductor electron devices, the interest of the technical community shifted away from circuit theory. Twenty years later, when integrated circuit technology began an explosive growth, circuit theory was again left behind in the shadow of rapidly progressing computer-aided design (CAD) technology. The present majority view is that electronic circuit theory stands in a subordinate position to CAD and to device processing technology. In the 1950s and 1960s, several new semiconductor devices were invented every year, and each new device seemed to have some interesting fundamental physical mechanisms that appeared worth investigating. Compared to attractive device physics, the problems of the semiconductor device circuit appeared less sophisticated and less attractive. Bright minds of the time drifted away from circuit theory to electron device physics. After thirty years, only one type of semiconductor device, the electron triode with several variations, survived, whereas hundreds of others went into oblivion.

Technical Assessment of Maglev System Concepts, 1998. The Government Maglev System Assessment Team operated from 1991 to 1993 as part of the National Maglev Initiative. They assessed the technical viability of four U.S. Maglev system concepts using the French TGV high-speed train and the German TR07 Maglev system as assessment baselines. Maglev, in general, offers advantages that include high speed, potential excellent system control, high capacity, low energy consumption, low maintenance, modest land requirements, low operating costs, and ability to meet a variety of transportation missions. Further, the U.S. Maglev concepts could provide superior performance to TR07 for similar cost or similar performance for less cost. They also could achieve both lower trip times and lower energy consumption along typical U.S. routes. These advantages result generally from the use of large gap magnetic suspensions, more powerful linear synchronous motors, and tilting vehicles. Innovative concepts for motors, guideways, suspension, and superconducting magnets all contribute to a potential for superior long-term performance of U.S. Maglev systems compared with TGV and TR07.
