

The Depot Fluphenazines: A Reappraisal After 10 Years' Clinical Experience

BY FRANK J. AYD, JR., M.D.

The author reviews the information gathered during the past 10 years of clinical experience with depot fluphenazines. He details the types of patients who are most likely to benefit from therapy with injectable drugs, the techniques of this therapy, the therapeutic efficacy and side effects of the drugs, and how they interact with other medications. Although he concludes that depot fluphenazines are safe and effective, he cautions clinicians that the starting dose and the intervals between injections must be carefully selected for each patient and that such factors as age, physical condition, diagnosis, and drug history must be taken into consideration.

PSYCHIATRY HAS EXPERIENCED a number of significant advances in this century, including the development of psychopharmacotherapy, the effectiveness of which depends on a variety of factors. One of the most important of these factors is the actual ingestion of adequate doses of pharmacotherapeutic drugs by patients.

Unfortunately, despite ample evidence that improvement can be achieved and sustained by the taking of an antipsychotic such as a neuroleptic or lithium for as long as it is required and despite all of our efforts, a large number of patients, particularly schizophrenic patients, will not take medication regularly after release from the hospital. We are therefore faced with a merry-go-round kind of process created by the discharges and readmissions of patients whose maintenance medication outside of the hospital has been reduced to inadequate levels or discontinued.

In every psychiatric hospital there are patients who could be released if they could be relied on to take medication. It has been estimated that 20 percent or more of hospitalized patients fail to take their drugs consistently

despite supervision, thereby impeding their rehabilitation. These drug defectors constitute a large segment of the world's psychiatric population. They have been and are a major therapeutic challenge.

What has been needed for patients who patently require chemotherapy but are unreliable drug takers has been a long-acting depot injectable neuroleptic. Such a preparation would remove responsibility for taking medicine from patients unable to assume it. This would assure physicians that patients are getting their medication and enable them to return more patients to the community and to keep them there. The development of fluphenazine enanthate, fluphenazine decanoate, flupenthixol decanoate, perphenazine enanthate, fluspirilene, pipothiazine undecylenate, and pipothiazine palmitate¹ has made this possible—a most important step forward in the treatment of certain psychiatric patients.

The first of the depot neuroleptics were fluphenazine enanthate and fluphenazine decanoate. These preparations have been administered to thousands of patients throughout the world during the past 10 and 9 years, respectively. Patients have had injections of various doses of these drugs at intervals ranging from a few hours to 8 weeks; some patients have received depot fluphenazines continuously for as long as 7 years. The information garnered from this vast clinical experience is the subject of this review.

CLINICAL INDICATIONS

Until the safety and efficacy of the depot fluphenazines could be established, the early clinical trials of these compounds were restricted to physically healthy hospitalized chronic schizophrenic patients between 20 and 50 years old who were receiving oral fluphenazine. The results of these trials (1-8) verified that the depot fluphenazines were efficacious and safe for a substantial percentage of
