## 1. Introduction

Metallic materials are mostly a combination of metallic elements, such as iron, aluminum, magnesium, titanium and manganese, which may also include small amounts of non-metallic elements, such as carbon, nitrogen and oxygen. As the first materials that humans discovered and applied, metallic materials not only play significant roles in human civilization but have also been widely and irreplaceably used in modern engineering. This is due to the fact that their great potential in terms of properties, quantities and qualities could evolve and renew with growing demand, and their remarkably complex properties are adaptable to the requirements of daily life and technology. Therefore, it is necessary to endlessly seek new metallic materials that have outstanding mechanical properties or modify existing materials to improve their mechanical properties; in this way, an in-depth understanding of the deformation, fracture and microstructure of various metallic materials is of particular significance.

As is well known, the deformation and fracture mechanisms of materials are strongly dependent on their initial microstructures (e.g., grain size, grain boundary character, inclusion, precipitate, phase composition, microstructural and chemical nonuniformity), which play a determining role in defining their mechanical properties. In addition, understanding the evolution of a microstructure during deformation is also extremely important for understanding the deformation and fracture mechanisms.

## 2. Contributions

Eleven papers, including two review papers and nine research papers, have been published focusing on the microstructure-related deformation and fracture behavior of steels, superalloys, titanium alloys and so on. Subsequently, an overview of the contributions is given as follows:

The two review papers summarize the technology and methods deployed in the exploration of fractured microstructures and improving the mechanical properties of metallic materials. Sánchez et al. [1] reviewed the adoption of mini-CT specimens for the fracture characterization of ferritic steels, particularly focusing on those used in the nuclear industry. The main existing results are displayed, and the main scientific and technical issues are thoroughly discussed. Li et al. [2] summarized the recent progress in the theoretical models and mechanisms of twin-related grain boundary engineering (GBE) optimization. An appropriate GBE treatment has been confirmed to be an effective pathway to improve some special mechanical properties (e.g., high-temperature tension, creep, low-cycle fatigue, etc.); thus, it is a feasible method for the development of high-performance metallic materials.

Steel materials are the most important metallic materials and have a wide range of applications, and the relevant investigations on the microstructure—property relationship are of the greatest importance. Qiu and Inoue [3] traced the evolution of Poisson's ratio during the tensile deformation process in a low-carbon hot-rolled steel. The results revealed that the average Poisson's ratio could not accurately express the local Poisson's ratio in the discontinuous-yielding regime, and the Poisson's ratio varied significantly within a plastic
